SUBSTITUTED BICYCLIC HETEROARYL COMPOUNDS

This application is a divisional application of U.S. patent application Ser. No. 14/347,893, filed Mar. 27, 2014, which claims priority to national phase application under 35 U.S.C. §371 of International Patent Application No. PCT/US2012/057406, filed Sep. 27, 2012, which claims priority to provisional application U.S. 61/539,570, filed Sep. 27, 2011, the contents of which are herein incorporated by reference.

The present invention generally relates to substituted bicyclic heteroaryl compounds useful as CYP17 inhibitors. Provided herein are substituted bicyclic heteroaryl compounds, compositions comprising such compounds, and methods of their use. The invention further pertains to pharmaceutical compositions comprising at least one compound according to the invention that is useful for the treatment of conditions related to the CYP17 enzyme, such as cancer and other proliferative diseases.

Prostate cancer is the second leading cause of cancer related mortality in American men. In 2007, there were 218,890 new cases with 27,000 deaths associated with prostate cancer. It is well known that androgens, such as testosterone and dihydrotestosterone, drive the growth of the prostate as well as prostate cancer at the level of the androgen receptor. The standard of care for advanced hormone sensitive prostate cancer involves surgical or chemical castration with a leutenizing releasing hormone agonist/antagonist to remove the androgens produced in the gonads from circulation. However, approximately 90% of androgens are produced in the testes with the remaining 10% being produced through the action of the adrenal gland. Thus, castration does not alleviate the action of all androgens. Further once a patient progresses to castration resistant prostate cancer, androgens are also produced at the level of the tumor, making treatment with anti-androgens more difficult.

The cytochrome P450 CYP17 is responsible for the biosynthesis of both dihydroepiandrosterone and androstenedione which are precursors of both androgens and estrogen. Thus the production of all androgens and estrogens produced in the human body is mediated by CYP17. Blocking this enzyme would inhibit the production of gonadal, adrenal and tumoral androgens and could offer a new treatment option for prostate cancer and estrogen receptor-positive breast cancer patients.

Clinical proof-of-concept for CYP17 as a target for prostate cancer has been achieved with the antifungal ketoconazole and the steroidal CYP17 inhibitor abiraterone, which has progressed to Phase III clinical trials for prostate cancer.

There remains a need for compounds that are useful as inhibitors of CYP17 enzymes.

Applicants have found potent compounds that have activity as CYP17 inhibitors. These compounds are provided to be useful as pharmaceuticals with desired stability, bioavailability, therapeutic index, and toxicity values that are important to their drugability.

DEFINITIONS

The features and advantages of the invention may be more readily understood by those of ordinary skill in the art upon reading the following detailed description. It is to be appreciated that certain features of the invention that are, for clarity reasons, described above and below in the context of separate embodiments, may also be combined to form a single embodiment. Conversely, various features of the invention that are, for brevity reasons, described in the context of a single embodiment, may also be combined so as to form sub-combinations thereof. Embodiments identified herein as exemplary or preferred are intended to be illustrative and not limiting.

Unless specifically stated otherwise herein, references made in the singular may also include the plural. For example, “a” and “an” may refer to either one, or one or more.

Unless otherwise indicated, any heteroatom with unsatisfied valences is assumed to have hydrogen atoms sufficient to satisfy the valences.

The definitions set forth herein take precedence over definitions set forth in any patent, patent application, and/or patent application publication incorporated herein by reference.

Listed below are definitions of various terms used to describe the present invention. These definitions apply to the terms as they are used throughout the specification (unless they are otherwise limited in specific instances) either individually or as part of a larger group.

Throughout the specification, groups and substituents thereof may be chosen by one skilled in the field to provide stable moieties and compounds.

In accordance with a convention used in the art,

is used in structural formulas herein to depict the bond that is the point of attachment of the moiety or substituent to the core or backbone structure.

14

The terms “halo” and “halogen,” as used herein, refer to F, Cl, Br, and I.

The term “alkyl” as used herein, refers to both branched and straight-chain saturated aliphatic hydrocarbon groups containing, for example, from 1 to 12 carbon atoms, from 1 to 6 carbon atoms, and from 1 to 4 carbon atoms. Examples of alkyl groups include, but are not limited to, methyl (Me), ethyl (Et), propyl (e.g., n-propyl and i-propyl), butyl (e.g., n-butyl, i-butyl, sec-butyl, and t-butyl), and pentyl (e.g., n-pentyl, isopentyl, neopentyl), n-hexyl, 2-methylpentyl, 2-ethylbutyl, 3-methylpentyl, and 4-methylpentyl. When numbers appear in a subscript after the symbol “C”, the subscript defines with more specificity the number of carbon atoms that a particular group may contain. For example, “C₁₋₆ alkyl” denotes straight and branched chain alkyl groups with one to six carbon atoms.

As used herein, “alkylenyl” refers to a bivalent alkyl radical having the general formula $-(CH_2)_n-$, where n is 1 to 10. Non-limiting examples include methylene, dimethylene, trimethylene, tetramethylene, pentamethylene, and hexamethylene. For example, “C₁₋₆alkylene” denotes straight and branched chain alkylene groups with one to six carbon atoms. Further, for example, “C₀₋₄alkylene” denotes a bond and straight and branched chain alkylene groups with one to four carbon atoms.

The term “alkynyl” refers to a straight or branched chain hydrocarbon radical containing from 2 to 12 carbon atoms and at least one carbon to carbon triple bond. Exemplary such groups include ethynyl. For example, “C₂₋₆ alkynyl” denotes straight and branched chain alkynyl groups with two to six carbon atoms.

The term “fluoroalkyl” as used herein is intended to include both branched and straight-chain saturated aliphatic hydrocarbon groups substituted with one or more fluorine atoms. For example, “C₁₋₄fluoroalkyl” is intended to include C₁, C₂, C₃, and C₄ alkyl groups substituted with one or more fluorine atoms. Representative examples of fluoroalkyl groups include, but are not limited to, $-CF_3$ and $-CH_2CF_3$.

The term “cyano” refers to the group $-CN$.

The term “cycloalkyl,” as used herein, refers to a group derived from a non-aromatic monocyclic or polycyclic hydrocarbon molecule by removal of one hydrogen atom from a saturated ring carbon atom. Representative examples of cycloalkyl groups include, but are not limited to, cyclopropyl, cyclopentyl, and cyclohexyl. When numbers appear in a subscript after the symbol “C”, the subscript defines with more specificity the number of carbon atoms that a particular cycloalkyl group may contain. For example, “C₃₋₆ cycloalkyl” denotes cycloalkyl groups with three to six carbon atoms.

The term “alkoxy,” as used herein, refers to an alkyl group attached to the parent molecular moiety through an oxygen atom, for example, methoxy group ($-OCH_3$).

“Fluoroalkoxy” and “ $-O$ (fluoroalkyl)” represent a fluoroalkyl group as defined above attached through an oxygen linkage ($-O-$). For example, “C₁₋₄fluoroalkoxy” is intended to include C₁, C₂, C₃, and C₄ fluoroalkoxy groups.

The term “aryl,” as used herein, refers to a group of atoms derived from a molecule containing aromatic ring(s) by removing one hydrogen that is bonded to the aromatic ring(s). Representative examples of aryl groups include, but are not limited to, phenyl, naphthyl, indanyl, indenyl, and 1,2,3,4-tetrahydronaphth-5-yl.

The term “benzyl,” as used herein, refers to a methyl group in which one of the hydrogen atoms is replaced by a phenyl group.

The term "heteroatom" refers to oxygen (O), sulfur (S), and nitrogen (N).

The term "heteroaryl" refers to substituted and unsubstituted aromatic 5- or 6-membered monocyclic groups and 9- or 10-membered bicyclic groups which have at least one heteroatom (O, S or N) in at least one of the rings, said heteroatom-containing ring preferably having 1, 2, or 3 heteroatoms independently selected from O, S, and/or N. Each ring of the heteroaryl group containing a heteroatom can contain one or two oxygen or sulfur atoms and/or from one to four nitrogen atoms provided that the total number of heteroatoms in each ring is four or less and each ring has at least one carbon atom. The fused rings completing the bicyclic group may contain only carbon atoms and may be saturated, partially saturated, or unsaturated. The nitrogen and sulfur atoms may optionally be oxidized and the nitrogen atoms may optionally be quaternized. Heteroaryl groups which are bicyclic or tricyclic must include at least one fully aromatic ring but the other fused ring or rings may be aromatic or non-aromatic. The heteroaryl group may be attached at any available nitrogen or carbon atom of any ring. The heteroaryl ring system may be unsubstituted or may contain one or more substituents.

Exemplary monocyclic heteroaryl groups include pyrrolyl, pyrazolyl, pyrazolinyl, imidazolyl, oxazolyl, isoxazolyl, thiazolyl, thiadiazolyl, isothiazolyl, furanyl, thiophenyl, oxadiazolyl, pyridinyl, pyrazinyl, pyrimidinyl, pyridazinyl, and triazolyl.

As used herein, "pharmaceutically acceptable salts" refer to derivatives of the disclosed compounds wherein the parent compound is modified by making acid or base salts thereof. Examples of pharmaceutically acceptable salts include, but are not limited to, mineral or organic acid salts of basic residues such as amines; and alkali or organic salts of acidic residues such as carboxylic acids. The pharmaceutically acceptable salts include the conventional non-toxic salts or the quaternary ammonium salts of the parent compound formed, for example, from non-toxic inorganic or organic acids. The pharmaceutically acceptable salts of the present invention can be synthesized from the parent compound which contains a basic or acidic moiety by conventional chemical methods. Generally, such salts can be prepared by reacting the free acid or base forms of these compounds with a stoichiometric amount of the appropriate base or acid in water or in an organic solvent, or in a mixture of the two; generally, nonaqueous media like ether, ethyl acetate, ethanol, isopropanol, or acetonitrile are preferred. "Stable compound" and "stable structure" are meant to indicate a compound that is sufficiently robust to survive isolation to a useful degree of purity from a reaction mixture, and formulation into an efficacious therapeutic agent. The present invention is intended to embody stable compounds.

"Therapeutically effective amount" is intended to include an amount of a compound of the present invention alone or an amount of the combination of compounds claimed or an amount of a compound of the present invention in combination with other active ingredients effective to act as an antagonist of CYP17 enzyme, or effective to treat cancer.

As used herein, "treating" or "treatment" cover the treatment of a disease-state in a mammal, particularly in a human, and include: (a) preventing the disease-state from occurring in a mammal, in particular, when such mammal is predisposed to the disease-state but has not yet been diagnosed as having it; (b) inhibiting the disease-state, i.e., arresting its development; and/or (c) relieving the disease-state, i.e., causing regression of the disease state.

Compounds of the present invention may contain one or more additional asymmetric carbon atoms and therefore exist in two or more stereoisomeric forms. The present invention includes all of the possible individual stereoisomers, the individual tautomeric forms thereof, together with mixtures thereof. Separation of diastereoisomers may be achieved by conventional techniques, e.g., by fractional crystallization, chromatography or HPLC of a stereoisomeric mixture of a compound of the present invention, or a suitable salt or derivative thereof. An individual enantiomer of the compound may also be prepared from a corresponding optically pure intermediate or by resolution, such as by HPLC of the corresponding racemate using a suitable chiral support or by fractional crystallization of the diastereoisomeric salts formed by reaction of the corresponding racemate with a suitable optically active acid or base, as appropriate. All stereoisomers of the compounds of the instant invention are contemplated, either in admixture or in pure or substantially pure form.

The compounds of the present invention are intended to include all isotopes of atoms occurring in the present compounds. Isotopes include those atoms having the same atomic number but different mass numbers. By way of general example and without limitation, isotopes of hydrogen include deuterium and tritium. Isotopes of carbon include ^{13}C and ^{14}C . Isotopically-labeled compounds of the invention can generally be prepared by conventional techniques known to those skilled in the art or by processes analogous to those described herein, using an appropriate isotopically-labeled reagent in place of the non-labeled reagent otherwise employed.

Also embraced within this invention is a class of pharmaceutical compositions comprising the compound of Formula (I) or a pharmaceutically acceptable salt thereof in association with one or more non-toxic, pharmaceutically-acceptable carriers and/or diluents and/or adjuvants (collectively referred to herein as "carrier" materials) and, if desired, other active ingredients. The compounds of Formula (I) may be administered by any suitable route, preferably in the form of a pharmaceutical composition adapted to such a route, and in a dose effective for the treatment intended. The compounds and compositions of the present invention may, for example, be administered orally, mucosally, or parentally including

18

intravascularly, intravenously, intraperitoneally, subcutaneously, intramuscularly intrasternally and infusion techniques, in dosage unit formulations containing conventional pharmaceutically acceptable carriers, adjuvants, and vehicles. For example, the pharmaceutical carrier may contain a mixture of mannitol or lactose and microcrystalline cellulose. The mixture may contain additional components such as a lubricating agent, e.g., magnesium stearate and a disintegrating agent such as croscopovidone. The carrier mixture may be filled into a gelatin capsule or compressed as a tablet.

The pharmaceutically active compounds of this invention can be processed in accordance with conventional methods of pharmacy to produce medicinal agents for administration to patients, including humans and other mammals.

For oral administration, the pharmaceutical composition may be in the form of, for example, a tablet, capsule, suspension, or liquid. The pharmaceutical composition is preferably made in the form of a dosage unit containing a particular amount of the active ingredient. Examples of such dosage units are tablets or capsules. For example, these may contain an amount of active ingredient from about 0.5 to 2000 mg, preferably from about 0.5 to 500 mg, more preferably from about 0.5 to 150 mg. A suitable daily dose for a human or other mammal may vary widely depending on the condition of the patient and other factors, but, once again, can be determined using routine methods.

The amounts of compounds that are administered and the dosage regimen for treating a disease condition with the compounds and/or compositions of this invention depends on a variety of factors, including the age, weight, sex, the medical condition of the subject, the type of disease, the severity of the disease, the route and frequency of administration, and the particular compound employed. Thus, the dosage regimen may vary widely, but can be determined routinely using standard methods. A daily dose of about 0.01 to 100 mg/kg body weight, preferably between about 0.05 and about 50 mg/kg body weight and most preferably between about 0.05 to 20 mg/kg body weight, may be appropriate. The daily dose can be administered in one to four doses per day.

For therapeutic purposes, the active compounds of this invention are ordinarily combined with one or more adjuvants appropriate to the indicated route of administration. If administered orally, the compounds may be admixed with lactose, sucrose, starch powder, cellulose esters of alkanolic acids, cellulose alkyl esters, talc, stearic acid, magnesium stearate, magnesium oxide, sodium and calcium salts of phosphoric and sulfuric acids, gelatin, acacia gum, sodium alginate, polyvinyl alcohol, and/or polyvinylpyrrolidone, and then tableted or encapsulated for convenient administration. Such capsules or tablets may contain a controlled-release formulation as may be provided in a dispersion of active compound in hydroxypropylmethyl cellulose.

The oily phase of the emulsions comprising compounds of Formula (I) may be constituted from known ingredients in a known manner. While the phase may comprise merely an emulsifier, it may comprise a mixture of at least one emulsifier with a fat or an oil or with both a fat and an oil. Preferably, a hydrophilic emulsifier is included together with a lipophilic emulsifier which acts as a stabilizer. It is also preferred to include both an oil and a fat. Together, the emulsifier(s) with or without stabilizer(s) make-up the so-called emulsifying wax, and the wax together with the oil and fat make up the so-called emulsifying ointment base which forms the oily dispersed phase of the cream formulations. Emulsifiers and emulsion stabilizers suitable for use in the formulation of the present invention include Tween 60, Span 80, cetostearyl alcohol, myristyl alcohol, glyceryl monostearate, sodium lau-

ryl sulfate, glyceryl distearate alone or with a wax, or other materials well known in the art.

The choice of suitable oils or fats for the formulation is based on achieving the desired cosmetic properties, since the solubility of the active compound in most oils likely to be used in pharmaceutical emulsion formulations is very low. Thus, the cream should preferably be a non-greasy, non-staining and washable product with suitable consistency to avoid leakage from tubes or other containers. Straight or branched chain, mono- or dibasic alkyl esters such as diisoadipate, isocetyl stearate, propylene glycol diester of coconut fatty acids, isopropyl myristate, decyl oleate, isopropyl palmitate, butyl stearate, 2-ethylhexyl palmitate or a blend of branched chain esters may be used. These may be used alone or in combination depending on the properties required. Alternatively, high melting point lipids such as white soft paraffin and/or liquid paraffin or other mineral oils can be used.

Formulations for parenteral administration may be in the form of aqueous or non-aqueous isotonic sterile injection solutions or suspensions. These solutions and suspensions may be prepared from sterile powders or granules using one or more of the carriers or diluents mentioned for use in the formulations for oral administration or by using other suitable dispersing or wetting agents and suspending agents. The compounds may be dissolved in water, polyethylene glycol, propylene glycol, ethanol, corn oil, cottonseed oil, peanut oil, sesame oil, benzyl alcohol, sodium chloride, tragacanth gum, and/or various buffers. Other adjuvants and modes of administration are well and widely known in the pharmaceutical art. The active ingredient may also be administered by injection as a composition with suitable carriers including saline, dextrose, or water, or with cyclodextrin (i.e., CAPTISOL®), cosolvent solubilization (i.e., propylene glycol) or micellar solubilization (i.e., Tween 80).

The sterile injectable preparation may also be a sterile injectable solution or suspension in a non-toxic parenterally acceptable diluent or solvent, for example as a solution in propylene glycol. Among the acceptable vehicles and solvents that may be employed are water, Ringer's solution, and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose any bland fixed oil may be employed, including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid find use in the preparation of injectables.

The pharmaceutical compositions may be subjected to conventional pharmaceutical operations such as sterilization and/or may contain conventional adjuvants, such as preservatives, stabilizers, wetting agents, emulsifiers, and buffers. Tablets and pills can additionally be prepared with enteric coatings. Such compositions may also comprise adjuvants, such as wetting, sweetening, flavoring, and perfuming agents.

Pharmaceutical compositions of this invention comprise the compound of Formula (I), or a pharmaceutically acceptable salt thereof, and optionally an additional agent selected from any pharmaceutically acceptable carrier, adjuvant, and vehicle. Alternate compositions of this invention comprise a compound of the Formula (I) described herein, or a pharmaceutically acceptable salt thereof, and a pharmaceutically acceptable carrier, adjuvant, or vehicle.

Pharmaceutically acceptable carriers, adjuvants, and vehicles that may be used in the pharmaceutical compositions of this invention include, but are not limited to, ion exchangers, alumina, aluminum stearate, lecithin, self-emulsifying drug delivery systems (SEDDS) such as d-alpha-tocopherol polyethyleneglycol 1000 succinate, surfactants used in phar-

maceutical dosage forms such as Tweens or other similar polymeric delivery matrices, serum proteins, such as human serum albumin, buffer substances such as phosphates, glycine, sorbic acid, potassium sorbate, partial glyceride mixtures of saturated vegetable fatty acids, water, salts or electrolytes, such as protamine sulfate, disodium hydrogen phosphate, potassium hydrogen phosphate, sodium chloride, zinc salts, colloidal silica, magnesium trisilicate, polyvinyl pyrrolidone, cellulose-based substances, polyethylene glycol, sodium carboxymethylcellulose, polyacrylates, waxes, polyethylene-polyoxypropylene-block polymers, polyethylene glycol and wool fat. Cyclodextrins such as alpha-, beta-, and gamma-cyclodextrin, or chemically modified derivatives such as hydroxyalkylcyclodextrins, including 2- and 3-hydroxypropyl-cyclodextrins, or other solubilized derivatives may also be advantageously used to enhance delivery of compounds of the formulae described herein.

Utility

The compounds of Formula (I) are useful for the treatment of cancer, for example, cancers dependent upon androgen receptor signaling. These compounds inhibit the activity of the CYP17 enzyme, which is involved in biosynthesis of androgens and estrogens. Thus, the treatment comprises administering to the patient a compound of Formula (I) or a pharmaceutically acceptable salt or prodrug thereof.

In one embodiment, a method is provided for treating cancer comprising administering compound of Formula (I) or a pharmaceutically acceptable salt or prodrug thereof to a mammal in need thereof. The method of this embodiment can be used to treat a variety of cancers, including, but not limited to, breast cancer, ovarian cancer, and prostate cancer. Preferably, the method of this embodiment is used to treat prostate cancer or breast cancer. In one method of this embodiment, compound of Formula (I) is administered in a therapeutically effective amount.

In another method of this embodiment, a compound of Formula (I) is administered to treat breast cancer. Preferably, a therapeutically effective amount of Compound (I) is administered.

The amount of a compound of Formula (I) which is administered and the dosage regimen for treating a particular cancer depends on a variety of factors, including the age, weight, sex and medical condition of the subject, the type of disease, the severity of the disease, the route and frequency of administration, and the particular compound employed. Thus, the dosage regimen may vary widely, but can be determined routinely using standard methods. A daily dose of about 0.01 to 500 mg/kg body weight, preferably between about 0.05 and about 50 mg/kg body weight and most preferably between about 0.05 to 20 mg/kg body weight, may be appropriate may be appropriate. It may be especially useful to employ cytotoxic drug combinations wherein the two or more drugs being administered act in different manners or in different phases of the cell cycle, and/or where the two or more drugs have overlapping toxicities or side effects, and/or where the drugs being combined each has a demonstrated efficacy in treating the particular disease state manifested by the patient.

Accordingly, a compound of Formula (I) may be administered in combination with other anti-cancer treatments useful in the treatment of cancer or other proliferative diseases. The invention herein further comprises use of a compound of Formula (I) in preparing medicaments for the treatment of cancer, and/or it comprises the packaging of a compound of Formula (I) herein together with instructions that the compound be used in combination with other anti-cancer or cytotoxic agents and treatments for the treatment of cancer. The present invention further comprises combinations of a compound of Formula (I) and one or more additional agents in kit form, e.g., where they are packaged together or placed in separate packages to be sold together as a kit, or where they are packaged to be formulated together.

The compound of Formula (I) can be formulated or co-administered with other therapeutic agents that are selected for their particular usefulness in addressing side effects associated with the aforementioned conditions. For example, the compound of Formula (I) may be formulated with agents to prevent nausea, hypersensitivity and gastric irritation, such as antiemetics, and H₁ and H₂ antihistaminics.

Methods of Preparation

The compounds of the present invention may be prepared by synthetic routes that include processes analogous to those well-known in the chemical arts, particularly in light of the description provided herein. For illustrative purposes, general Schemes 1 to 20 below show general methods for preparing the compounds of the present invention, as well as key intermediates. For a more detailed description of the individual reaction steps, see the Example section below. Those skilled in the art will appreciate that other synthetic routes may be used to synthesize the inventive compounds. Although specific starting materials and reagents are depicted in the Schemes and discussed below, other starting materials and reagents can easily be substituted to provide a variety of compounds of the present invention. In addition, many of the compounds prepared by the methods below can be further modified in light of this disclosure using conventional chemistry well known to those skilled in the art.

As shown in Scheme 1, for instance, Cl-aryl or alkyl substituted benzoisoxazoles of type IA can be prepared from 3-bromo-2-fluorobenzaldehyde II via a Grignard addition into the aldehyde. The resultant alcohol III can be oxidized, by Dess-Martin periodinane for example, to afford the ketone of general structure IV. Treatment of the ketone with hydroxylamine can afford oxime V. Subsequently, cyclization to provide the corresponding benzoisoxazole VI will occur in

23

the presence of a base, such as NaH. Under standard Suzuki coupling conditions, benzoisoxazole VI can be coupled with a boronic ester or acid VII to furnish compounds of general structure IA.

The general structure of the aryl boronic ester or acid of type VII shown in Scheme 1 can be synthesized from the corresponding halide VIII by a palladium-mediated reaction with a source of boron, such as bis(pinacolato)diboron (Scheme 2). Alternatively halogen-metal exchange with aryl halide VIII and a subsequent reaction with triisopropyl borate will also afford boronic esters or acids of type VII.

24

Scheme 2

The general halides of type VIII used in the synthesis of aryl boronic ester or acid VII can originate from pyrimidyl ethers X (Scheme 3), pyrimidyl amines XI (Scheme 4), 4-alkyl or 4-aryl pyrimidines XIII (Scheme 5), 4-aryl pyridines XV (Scheme 6), and 4-cycloalkyl XVII or 4-alkyl pyridines XVII, XVIII (Scheme 7 and 8). Each of these halides can be synthesized in the following manner. The pyrimidyl ethers X can be generated from displacement of the corresponding pyrimidyl chloride IX with an alcohol and base. The pyrimidyl amines XI can be synthesized under the same reaction conditions from the pyrimidyl chloride IX and ammonia or a primary or secondary amine. 4-Alkyl and 4-aryl substituted pyrimidines XIII can be prepared by many methods well known to those skilled in the art. Scheme 5 depicts one such method where 5-bromopyrimidine XII can be treated with an alkyl or aryl lithium or a Grignard reagent to give the 4-substituted dihydropyrimidine. Subsequent oxidation by, for example, DDQ, then gives the desired 4-substituted pyrimidine XIII. In contrast, 4-aryl pyridines of general structure XV can be prepared by Suzuki coupling of boronic ester XIV with an aryl iodide under palladium catalysis. Substituted pyridines of type XVII and XVIII can be synthesized by deprotonation of 3-bromopyridine with a strong base such as LDA to generate an anion, and then a subsequent reaction with an alkyl or cycloalkyl ketone to give substituted pyridines of type XVII or treatment with an alkyl iodide to afford 4-alkyl pyridines of type XVIII. Finally, the pyrrolopyrimidine XX depicted in Scheme 9 can be prepared from 5-bromopyrimidine XII. Addition of an alkyl lithium reagent to this commercially available starting material will give the corresponding 4-substituted dihydropyrimidine XIX. Subsequent oxidation by, for example, DDQ then gives the desired 4-substituted pyrimidine. Treatment of this intermediate XIX with an organic acid, such as formic acid, will generate the corresponding aldehyde. Further reaction of the aldehyde with Burgess reagent will promote cyclization to the desired pyrrolopyrimidine XX.

The compounds of type IA depicted in Scheme 1 can alternatively be synthesized by a Pd (II) mediated coupling of benzoisoxazole VI with a boron source XXI, such as 4,4,5,5-tetramethyl-1,3,2-dioxaborolane, to form benzoisoxazole ester or acid XXII (Scheme 10). Reaction of intermediate XXII with a heteroaryl halide VIII under standard Suzuki conditions can afford analogs of general structure IA.

Scheme 10

Preparation of benzoisoxazoles linked to a heteroatom at C3 can be accomplished by literature methods that are well known to those skilled in the art. Scheme 11 depicts a commonly used method for the preparation of benzoisoxazole IB from commercially available 3-bromo-2-fluorobenzonitrile or from 3-fluoro-4-iodopicolinonitrile XXIII, which is available in one step from the iodination of 3-fluoropicolinonitrile XXVII (Scheme 12). A standard Suzuki coupling of the general aryl halide XXIII with boronic ester or acid VII can afford biaryls of type XXIV. Subsequently, reaction of this intermediate with N-hydroxyacetamide induces cyclization and formation of benzoisoxazole amine XXV. Treatment of the primary amine with sodium nitrite and hydrochloric acid can provide the corresponding benzoisoxazole chloride XXVI. Finally, displacement of the aryl chloride with an alcohol, thiol or amine in the presence of a base will afford analogs of general structure IB.

Scheme 11

Scheme 12

Another method of generating benzonitrile XXIV utilized in Scheme 11, when $X=C$, can be achieved by a standard Suzuki reaction between heteroaryl halide VIII and commercially available boronic ester or acid XXVIII (Scheme 13).

Scheme 13

Additionally, if aryl, heteroaryl, alkyl, or cycloalkyl groups are desired at C3 of the general structure IA or IC, those skilled in the art can prepare such compounds from intermediate XXIV (Scheme 14). A Grignard addition into the nitrile and a subsequent hydrolysis of the in situ generated imine with HCl can provide ketone XXIX. Further reaction of intermediate XXIX with hydroxylamine will afford oxime XXX, which can be cyclized to the corresponding benzoisoxazole of general structure IA or IC in the presence of a base, such as NaH.

Furthermore, benzoisoxazoles linked to a variety of substituted pyrimidines of general structure IA, IB, or IC can be

29

synthesized from compounds of general structure XXXI (Scheme 15). Treatment of compound XXXI with peroxyacetic acid and sulfuric acid can provide hydroxylated intermediate XXXII. Reaction of the pyrimidinol with phosphorus oxychloride will furnish chloropyrimidine XXXIII. Finally, displacement of the chloride with an alcohol or amine can lead to compounds of general structure IA, IB, or IC.

Scheme 15

Those skilled in the art will also find that substituted pyrimidines linked to benzisoxazoles of general structure IA or IC can be synthesized from biaryl intermediate XXXIV (Scheme 16). Similar to the reaction sequence shown in Scheme 15, treatment of the pyrimidine with peroxyacetic acid and sulfuric acid will give pyrimidinol XXXV. Subsequently, a Grignard addition into the nitrile followed by hydrolysis with hydrochloric acid can lead to a variety of substituted ketones of type XXXVI. Reaction of this ketone with hydroxylamine will furnish oxime XXXVII. As previously described, cyclization to the corresponding benzisoxazole can be accomplished with base. Conversion of the pyrimidinol XXXII to the chloropyrimidine XXXIII can occur by reaction with phosphorus oxychloride. Lastly, displacement of the chloride with an alcohol or amine can lead to compounds of general structure IA or IC.

30

Scheme 16

Benzothiophenes or thienopyridines of general structure IE can be synthesized from the commercially available alcohol XXXVIII (Scheme 17). Halogenation of this starting material with phosphorus oxychloride or bromide can provide an intermediate of type XXXIX. Following a standard Suzuki coupling of (hetero)aryl halide XXXIX with a general boronic ester or acid VII, an analog of type XXXX can be formed. Functionalization at C3 can be accomplished by a

31

bromination step and then a Pd(0)-mediated Stille coupling of intermediate XXXXI with stannane XXXXII to give compounds of general structure IE.

Alternatively, compounds of general structure IE can also be synthesized via a standard Suzuki coupling of intermediate XXXXI with boronic ester or acid XXXXIII (Scheme 18).

Benzothiophenes of general structure IF can be synthesized from benzo[b]thiophen-4-amine XXXXIII (Scheme 19). Treatment of this commercially available starting material with methanesulfonyl chloride will afford sulfonamide XXXXV. Iodination of this intermediate with I₂ in pyridine will provide the aryl iodide XXXXIV. Subsequently, a standard Suzuki coupling of this compound with a boronic ester or acid VII can furnish analogs of general structure IF.

32

Scheme 19

Benzoisoxazoles of general structure IG can be synthesized from 2-amino-6-fluorobenzonitrile XXXXVII (Scheme 20). Iodination of this commercially available starting material with a reagent, such as IC1, will provide aryl iodide XXXXVIII. Reaction of the primary amine with methanesulfonyl chloride and pyridine will give sulfonamide XXXXIX. Following ring closure to benzoisoxazole XXXXX by reaction of intermediate XXXXIX with N-hydroxyacetamide, a standard Suzuki coupling of benzoisoxazole XXXXX with boronic ester or acid VII can lead to compounds of general structure IG.

Biological Assays

The pharmacological properties of the compounds of this invention may be confirmed by a number of biological assays. The exemplified biological assays, which follow, have been carried out with compounds of the invention and/or salts thereof.

CYP17 Total SPA Assay

The assays were performed in U-bottom 384-well optiplates. The final assay volume was 15 μ l prepared from 7.5 μ l additions of microsomes (prepared as a high-speed pellet from homogenized HEK2 cells stably transfected with CYP17), substrates (3H-Pregnenolone and NADPH) and test compounds in assay buffer (50 mM Potassium phosphate pH 7.2, 10% glycerol). The reaction was initiated by the combination of the microsomes and substrates in wells containing

164

compound. The reaction was incubated at room temperature for 45 minutes and terminated by adding 7.5 μ l of 0.2N HCl to each well. Following an incubation period of 10 minutes, anti-DHEA-coated SPA beads were added to the terminated reaction. The plate was sealed and incubated overnight with shaking at 4° C. The beads were allowed to settle in the plate for 1 hour and the plate read on a TOPCOUNT® (Perkin-Elmer) plate reader.

Inhibition data were calculated by comparison to no enzyme control reactions for 100% inhibition and vehicle-only reactions for 0% inhibition. The final concentration of reagents in the assays are NADPH, 2 mM; 3H-Pregnenolone, 1 μ M; microsomes, 1.25 μ g/ml; Anti-DHEA-SPA beads (0.125 mg/well) in 0.5% Triton X-100 and DMSO, 0.05%. Dose response curves were generated to determine the concentration required inhibiting 50% of enzyme activity (IC_{50}). Compounds were dissolved at 10 mM in dimethylsulfoxide (DMSO) and evaluated at eleven concentrations, each in duplicate. IC_{50} values were derived by non-linear regression analysis.

Table 5 below lists the IC_{50} values for the following examples of this invention measured in the Total CYP17 SPA Assay hereinabove. The compounds of the present invention, as exemplified by the following examples, showed Human CYP17 SPA IC_{50} values of less than 1 μ M.

CYP17 Lyase Assay

Human CYP17 was expressed in HEK293 cells and microsomal preparations were made and subsequently used as the source of enzyme in the lyase assay. The reaction consists of 200 nM [3H]-Hydroxypregnenolone (ARC), 200 nM 17-Hydroxypregnenolone (Sigma), 2 mM NADPH (Cal-Biochem), and CYP17-HEK293 microsomes which were incubated in the presence of DMSO or test compounds for 20 minutes at room temperature. Compounds were dissolved in DMSO and serially diluted. The reaction was stopped by the addition of 0.2 N HCl and the product was captured using anti-mouse YSi SPA beads (GE) conjugated to an anti-DHEA monoclonal antibody (Abcam). Signal intensity determined by a Packard Top Count was used to calculate percent inhibition and IC_{50} values.

CYP17 Hydroxylase Assay

E. coli was transformed to express active human CYP17 and membranes prepared from the transformed *E. coli* were used as the source of enzyme. The reaction was carried out in

a 50 uL final volume containing 200 nM hCYP17 membranes, 25 μM Pregnenolone (Sigma), 7 mM NADPH (Cal-Biochem), 1 μM cytochrome P450 reductase (Invitrogen), and 50 mM sodium phosphate buffer, pH 7.3. The IC₅₀ determination of compounds dissolved in 100% DMSO was done by serial dilution into the assay buffer to a final concentration of 0.2% DMSO. The reaction was incubated at 37° C. for 120 minutes and stopped by the addition of 200 uL of 0.02N HCl in acetonitrile. Samples were then spun at 750000 g and 200 uL of the supernatant was transferred to a clean tube for analysis. The product of the reaction, 17 alpha pregnenolone, was measured via LC/MS.
